## Introduction

Industrial bioreactors are characterized by non-uniform fluidic conditions due to poor mixing which results in heterogeneous substrate concentration profiles and consequently, low yield reaction systems. The impeller system used is a crucial component to promote the mixing inside bioreactors. This work is an investigation of the design of an impeller of a BIO-AQUA system. BIO-AQUA is a Danish company specialized in designing and developing water solutions for industrial and environmental challenges. The company has developed a fixed film biological reactor for aerobic decomposition of organic matter. The dispersion of air into the system is achieved by using a gas-inducing impeller. The main goal of this computational investigation is to study the impeller design influence on the performance of the system (mass flow sparged into the system and power consumption). Three designs of impellers with different types of blades were chosen for this study: rectangular blades, rectangular blades with round edges and round blades. The computational fluid dynamics (CFD) software, ANSYS CFX® was used as a tool in order to model and analyze the performance of the gas-inducing impeller.

### Scheme of a general gas-induced impeller

The rotational velocity of the impeller leads to the acceleration of the liquid around it and to a decrease in pressure. The gas-inducing impeller generates a pressure difference in the hollow shaft and is therewith transporting air from the opening at the top of a hollow shaft into the liquid.

### Geometry modelled using Computational Fluid Dynamics

## Results

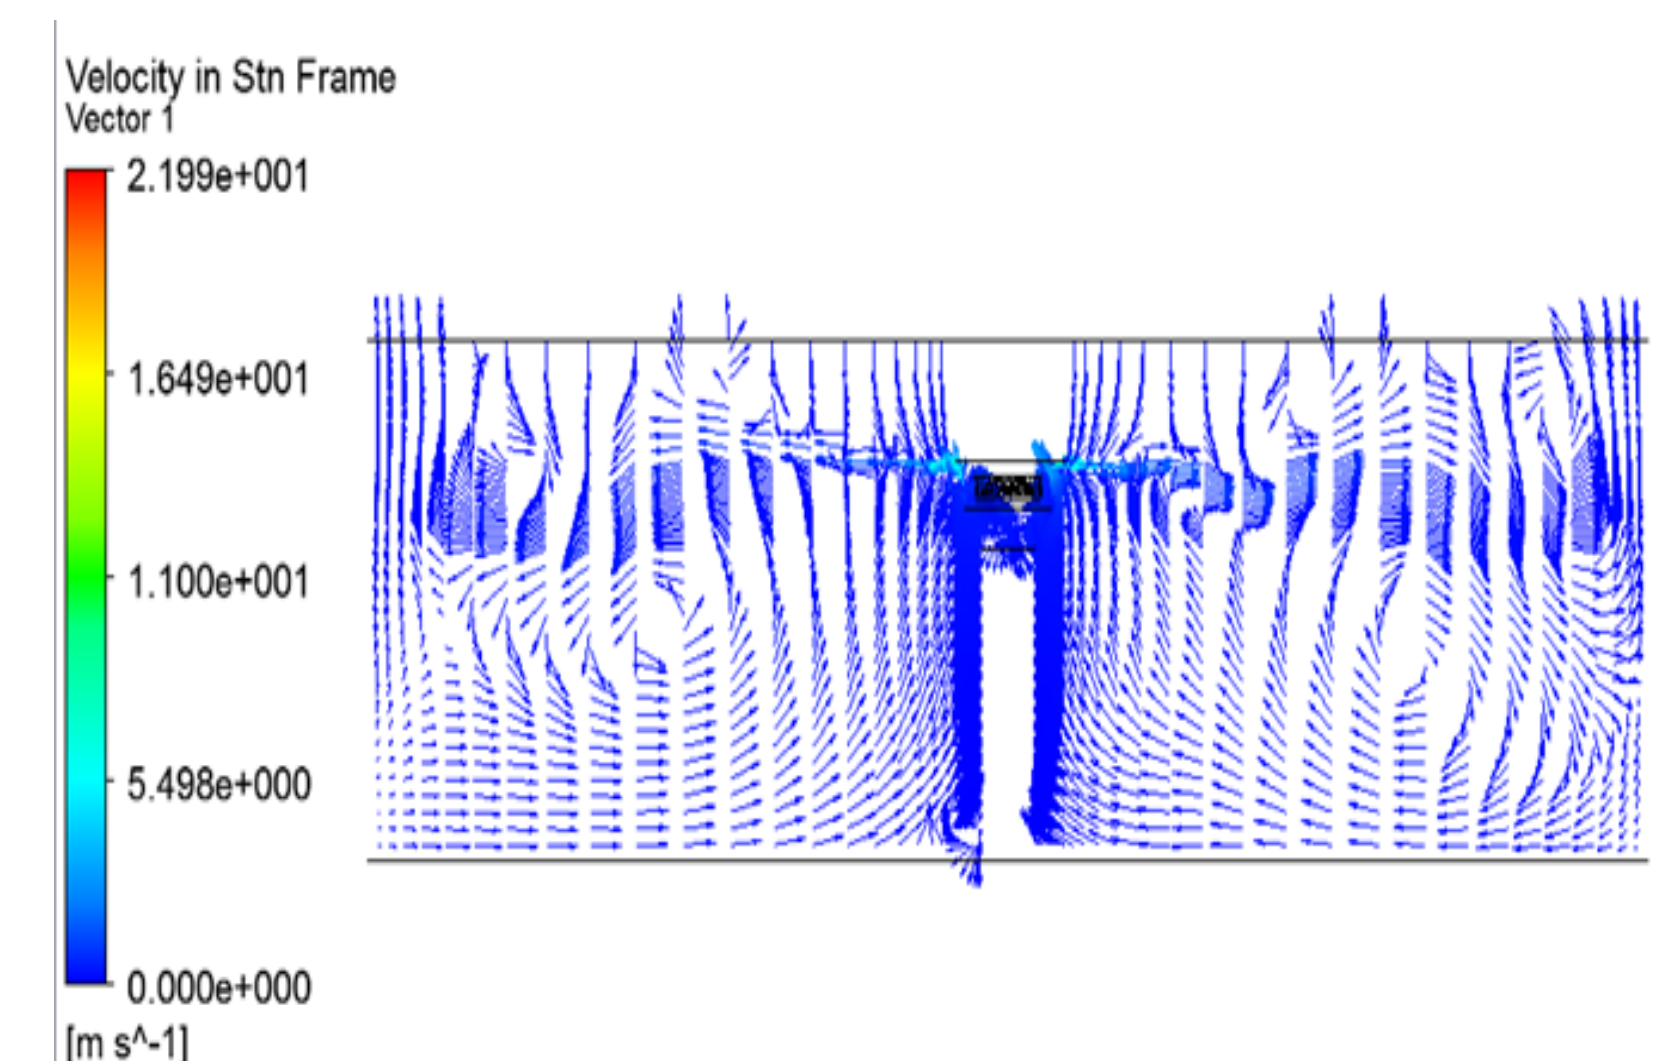

### Rectangular blades

### Rectangular blades with round edges

### Round blades

## Conclusions

The results of this test design have shown that the changes made on the blades shape of the impeller have a significant impact on power consumption and on the mass flow sparged into the the system. Even though the blades with more round edges consumed more power than the original design (between 21-27%), they also sparged between 59% and 63,5% more flow into the vessel. The company will make a decision of the type of blades to be used in the system according to the balance between the power consumption and mass flow. In conclusion, this study has demonstrated how useful CFD is on designing new systems and consequently, minimizing experimental work in order to find best performing system.

### Test design results—power consumption and mass flowrate
